TITLE: Dynamical systems with a countably multiple Lebesgue spectrum. I

PERIODICAL: Akademiya nauk SSSR. Izvestiya seriya Matematicheskaya,
v. 25, no. 6, 1961, 899 - 924

TEXT: The author shows that certain geometric properties of the motion of a dynamical system imply a countably multiple Lebesgue spectrum of the system, similarly to the case of a discrete spectrum. The method used is based on the concepts of K-automorphism and K-flow. K-automorphisms have been studied by V. A. Rokhlin (Izvestiya Ak. nauk SSSR, seriya matem., 25 (1961), 499 - 530). The author adopted some of Rokhlin's results for a dynamical system with continuous time. A measurable flow $\{S_t\}$ which is

given in a Lebesgue space M is said to be a K-flow if there exists a measurable partition ξ of M with the following properties:

I. $S_t \xi = \xi^t > \xi^{t_1} \text{ mod } 0$ for $t > t_1$. II. $\bigcup \xi^t = \xi \text{ mod } 0$. III. $\tilde{\Delta} \xi^t = \gamma \text{ mod } 0$

Dynamical systems with a ...

. $\{\cdot\}$ is an arbitrary measurable partition of M , ξ is the partition of M into its single points, and γ is the trivial partition $\{M\}$. A measurable flow $\{S_t\}$ is a group of automorphisms of M depending on one parameter t and satisfying the following condition: For each measurable subset $A \subset M$, the set of all pairs (x, t) with $S_t x \in A$ is measurable in $M \times (t)$. Conditions for the existence of a countably multiple Lebesgue component in the spectrum of a special flow are derived. General properties of a K-flow and of its spectrum are studied. Kolmogorov A. N. (Doklady Ak. nauk SSSR, 119, No. 5 (1958), 861 - 865.), Plesner L. I. (Doklady Ak. nauk SSSR, 23, No. 4 (1939), 327 - 330., 25, No. 9 (1950), 703 - 710.), and Gel'fand I. M. and Fomin S. V. (Uspekhi matem. nauk, 7, no. 1 (1952), 118 - 137.) are referred to. There are 24 references: 19 Soviet and 5 non-Soviet. TITLE: On limit theorems for stationary processes

PERIODICAL: Teoriya veroyatnostey i yeye primeneniya, v.7, no. 2, 1962,
213-219

TEXT: To every strictly stationary process $\xi(t)$, $-\infty < t < \infty$ there corresponds a system of closed σ -algebras $\mathcal{M}_{s_1}^{s_2}$ which are generated by the random variables $\xi(t)$ for $s_1 \leq t \leq s_2$. Assume that $\xi(t)$ is ergodic and satisfies the condition:

A : To every $\epsilon > 0$ there exists a $t(\epsilon) > 0$, an integer $n(\epsilon) = n$ and

sets A_0, A_1, \dots, A_n so that

d) $A_i \cap A_j = \emptyset$, $i \neq j$, $\bigcup_{i=0}^n A_i = \Omega$ (Ω is the space of all realizations

of $\xi(t)$.

e) $A_i \in \mathcal{M}_{-\infty}^0$, $i = 0, 1, \dots, n$

Card 1/4

On limit theorems for...

3/052/62/007/002/004/005
C111/C222

g) $P(A_0) < \epsilon$, $\sup_{i=1,\dots,n} |P(\Gamma_1 \cap \Gamma_2 / A_i) - P(\Gamma_1 / A_i)P(\Gamma_2 / A_i)| < \epsilon$,
 \sup is taken over $\Gamma_1 \in \mathcal{M}_{-\infty}^{\infty}$ and $\Gamma_2 \in \mathcal{M}_t^{\infty}$. Let

$$M\bar{\xi}(t) = 0 \text{ and } D_T(\bar{\xi}) = M(\bar{\xi}_T)^2.$$

$\xi(t)$ is denoted as a process with mixing, if for arbitrary measurable sets Γ_1 and Γ_2 and for $t \rightarrow \infty$

$$|P(s_t \Gamma_1 \cap \Gamma_2) - P(\Gamma_1)P(\Gamma_2)| \rightarrow 0,$$

and $\xi'(t) = S_T \xi(t) = \xi(t-T)$.

The following theorems are proved:

Theorem 1 : If for a process with mixing $\xi(t)$ which satisfies the condition A it holds $D_T(\xi) \rightarrow \infty$ for $T \rightarrow \infty$, then there exists a function $A(T)$ such that for the validity of the relation

$$\lim_{T \rightarrow \infty} P\left\{ \xi_T < x \sqrt{A(T)} \right\} = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^x \exp(-u^2/2) du$$

Card 2/4

5/352/62/007/002/004/005
C111/C222

On limit theorems for...

for every x , $-\infty < x < \infty$ the Lindeberg condition is sufficient : to every $\epsilon > 0$ there exist constants $N(\epsilon)$ and $T(\epsilon)$ such that for $T > T(\epsilon)$ it holds

$$\frac{1}{D_T(\xi)} \int_{|\xi_T| > N(\epsilon) \sqrt{D_T(\xi)}} (\xi_T)^2 dP < \epsilon. \quad (10)$$

Theorem 2 : If a regular process $\xi(t)$ satisfies condition A and the Lindeberg condition (10), then for every $c > 0$

$$A(cT)/A(T) \rightarrow c \quad (T \rightarrow \infty).$$

Theorem 3 : If $\xi(t)$ obeys the central limit theorem, then

$$c = \liminf_{T \rightarrow \infty} \frac{D_T(\xi)}{A(T)} > 0.$$

From the theorems there follows the possibility of constructing regular stationary processes which do not satisfy condition A and a fortiori the strong mixing condition of Rosenblatt (Ref. 1: A central limit

AUTHOR BAYUKOV, YU. D., SINAYEV A.N., TYAPKIN A.A. PA - 2699
TITLE Experimental Comparison of the Energy Spectra of γ -Quanta resulting from the Decay of Neutral Pions (which were created by 660 MeV-Protons on Carbon- and Lead-Nuclei).
(Eksperimental'noye sravneniye energeticheskikh spektrov kvantov ot raspada π^0 -mezenev, obrazovannykh na yadrakh ugleroda i svintsa pri etonami s energiyey 660 MeV, Russian.)
PERIODICAL Zhurnal Eksperim. i Teoret. Fiziki 1957, Vol 32, Nr 2,
 pp 385 - 386 (USSR).
Received: 5/1957 Reviewed: 6/1957
ABSTRACT For a more exact comparison of γ -quanta created on light and heavy nuclei the authors carried out relative measurements of the fluxes of γ -quanta within the various domains of the spectra mentioned above.
The angle of observation in the direction of motion of the protons amounted to 0°. Measurements were carried out by means of a magnetic double spectrometer with 12 channels. The targets consisting of lead and graphite fitted into the vacuum chamber of the accelerator were exchanged every minute.
At low energies of γ -quanta ($E_\gamma < 70$ MeV) a difference is noticed on the γ -quanta created on carbon and lead. This difference is connected apparently with the modification of the angular distribution of the neutral pions.

TITLE: A Multichannel Pair γ -Spectrometer. I. Calculation of the Main Characteristics of the γ -Spectrometer (Mnogokanal'nyy parnyy gamma-spektrometr. I. Raschet osnovnykh kharakteristik-gamma-spektrometra)

PERIODICAL: Pribory i tekhnika eksperimenta, 1958, Nr 6, pp 23-29
(USSR)

ABSTRACT: In a pair γ -spectrometer the energy of the quanta is determined by measuring the total energy of the components of the electron-positron pair formed in a thin converter. The first 2-channel pair spectrometer was built by Dzhelepov (Ref.). Later spectrometers built on this principle were widely used in measuring the spectra of hard γ -rays (Refs. 2 to 8). The electron and the positron leaving the converter were deflected by a magnetic field in different directions and for certain values of their energy they enter ionisation counters connected in coincidence. For a given intensity of the magnetic field and a fixed position of the counters, such a spectrometer will record a fraction of the pairs produced by γ -rays in a given energy range. In a simple 2-channel spectrometer in which one channel records the electrons and

Card 1/6

SOV/120-58-6-4/32

A Multichannel Pair γ -spectrometer. I. Calculation of the Main Characteristics of the γ -spectrometer

the other the positrons, an increase in the accuracy of measurement is associated with a marked decrease in the efficiency. Good energy resolution and high efficiency can only be simultaneously achieved in a multichannel spectrometer. In such a spectrometer the efficiency may be increased by a factor $n_1 n_2$ without loss of resolution, where n_1 and n_2 are the numbers of electron and positron counters. In such a spectrometer several energy intervals may be examined at the same time. A number of such multichannel spectrometers have been described (Refs. 5, 6 and 8). The question of a γ -spectrometer as a measuring instrument is determined by its efficiency and spectral sensitivity. In designing a multichannel system it is necessary to take into account the characteristics for the various pairs of channels of the spectrum. In this connection, a discussion is given in the present paper of the dependence of the efficiency and spectral sensitivity of the separate pairs of channels on various

Card 2/6

SOV/120-58-6-4/32

A Multichannel Pair γ -spectrometer. I. Calculation of the Main Characteristics of the γ -spectrometer

parameters of the spectrometer:

1) Spectral sensitivity: the basic diagram of a γ -spectrometer considered in this paper is shown in Fig.1, in which the meanings of the symbols employed are indicated. In view of the finite width of the counters, the spectrometer records γ -quanta in a certain energy interval from $E_{\gamma \text{ min}}$ to $E_{\gamma \text{ max}}$. The corresponding spectral sensitivity curve is then shown in Fig.2a and is of triangular form with a dispersion given by

$$\sigma_{I\gamma} = 1/6 \ell_c^2 / (r_1 + r_2)^2 \quad \text{where } \ell_c \text{ is the width of a}$$

counter and r_1 and r_2 are the distances from the converter to the centres of the counters, respectively. The effect of the width of the converter upon the spectral sensitivity is examined and it is shown that a converter of a finite width introduces a spread into the spectral line in the high energy region of γ -quanta. As the angle φ between the direction of motion of the γ -quanta and the

Card 3/6 straight line connecting the centre of the converter with

SOV/120-58-6-4/32

A Multichannel Pair γ -spectrometer. I. Calculation of the Main
Characteristics of the γ -spectrometer

the counter increases, the spread of the spectral line de-
creases. At $\varphi = 90^\circ$ the width of the spectral sensitivity
curve is independent of the converter width. The effect of
the converter width gives a distribution of the form shown
in Fig. 2b, which has a dispersion given by:

$$\sigma_2^2 = \frac{\lambda_k^4 \operatorname{ctg}^4 \varphi}{180 r_1^2 r_2^2} . \quad \text{The effect of multiple}$$

scattering in the converter is estimated and expressed. 2) are derived for this effect also. Finally, an estimate is given for the radiation loss experienced by the electron-positron pair on traversing the converter.
2) Efficiency: in this section the Bethe-Heitler expression for the probability of formation of a pair by a γ -quantum of

Card 4/6

SOV/120-58-6-4/32

A Multichannel Pair γ -spectrometer. I. Calculation of the Main Characteristics of the γ -spectrometer

energy E_γ is used (Ref.13) with a modification described by Bethe et al in Ref.22.

3) Multichannel system: in a multichannel spectrometer the electrons and positrons formed by γ -quanta of a given energy are recorded by a number of combinations of pairs of counters. The electronic circuit of such a spectrometer should record coincidences between pulses from each electron counter with pulses from any positron counter. Thus, any combination of one electron counter and one positron counter is, in fact, a 2-channel spectrometer. For a given geometry a spectrometer containing n channels records γ -quanta in $n-1$ energy intervals of different mean energy. In practice, one seeks to find the form of the spectrum and the absolute intensity in one of the energy intervals. To find the form of the spectrum it is sufficient to know the relative efficiency of recording for the different energy intervals, and this is given by Eq.(10). In order to obtain the absolute intensity in one of the energy intervals it is necessary to know the total absolute efficiency of recording of γ -quanta in one of the energy intervals. This problem is not treated.

TITLE: A Multichannel Pair γ -Spectrometer. II. Description of a
12-channel Spectrometer (Mnogokanal'nyy parnyy gamma-spek-
trometr. II. Opisaniye dvenadtsatikanal'nogo spektrometra)

PERIODICAL: Pribory i tekhnika eksperimenta, 1958, Nr 6, pp 30-40
(USSR)

ABSTRACT: Application of a multichannel pair spectrometer in synchro-
cyclotron work presents a number of specific requirements as
far as counters of the ionising particles and the electronic
system of the spectrometer are concerned. Since the beam
intensity is high and consists of short pulses of 200 to
300 μ s each at a repetition frequency of 40 to 80 pulses per
sec, it follows that the apparatus must be very fast. It is
desirable that the input blocks should have resolving times
not greater than 1 μ s. The large background intensity in
synchro-cyclotron work means that it is always necessary to
use a special selection system which records only electron-
positron pairs. For this reason, in the spectrometer each
component of a pair should be recorded by a number of counters
in coincidence with sufficiently low resolving time. The
Card 1/7 present paper describes a 12-channel γ -spectrometer which has

SOV/120-58-6-5/32

A Multichannel Pair γ -Spectrometer. II. Description of a 12-channel Spectrometer

been used over a number of years in studying the spectra of hard γ -rays and neutral π -meson decays (Refs.2-6). The first variant of the spectrometer was built in 1949. In 1951 and 1954 the spectrometer was modified to improve its characteristics. The spectrometer described here satisfies completely the above requirements and is based on the design calculations given in the previous paper (Ref.1) in this issue.

1) Magnetic system and geometry of the instrument.

The magnetic field is produced by an SP-56 electromagnet. Fig.1 shows the disposition of the counters for two types of demountable pole pieces. The gap between the poles is 1 cm and the maximum field in the gap is 18 000 oersted. The electromagnet current is stabilised to 0.1%. In studies of γ -ray spectra in the energy region 20 to 200 MeV, $2\phi = 180^\circ$ (Fig.1b) and in the energy region 100 to 450 MeV, $2\phi = 90^\circ$ (Fig.1a). In the former case semi-circular focussing of

Card 2/7

SOV/120-58-6-5/32

A Multichannel Pair γ -Spectrometer. II. Description of a 12-channel Spectrometer

electrons and positrons was used, and this led to increased efficiency (Ref.1) because it was possible to use wider and thicker converters. For γ -quanta in the energy range 450-600 MeV, $2\varphi = 90^\circ$ but the counters were at a larger distance from the converter. Copper converters were used (0.1, 0.3 and 0.5 mm, depending on the energy).

2) Resolving power and efficiency.

Fig.2 shows curves of the total spectral sensitivity for the 7th energy interval for various values of $E_{\gamma 0}$ and thicknesses T_k of the copper converters. These curves are based on the theoretical data given in the previous paper and are obtained by a statistical combination of the partial distributions due to a) width of the counters, b) width of the converter, c) multiple scattering and d) radiation. As can be seen, the form of the total spectral sensitivity curve is very nearly triangular, which means that the total spectral sensitivity is governed mainly by the width of the channels l_c (see Fig.1 of previous paper, p 24, this issue).

Card 3/7

SOV/120-58-6-5/32

A Multichannel Pair γ -Spectrometer. II. Description of a 12-channel Spectrometer

3) Counters and selection system. The counters used were proportional counters having a cylindrical stainless steel cathode, 10 mm in diameter and a molybdenum filament 0.1 mm in diameter. They were filled with $(\text{CH}_2(\text{OCH}_3)_2$) at a pressure of 160 to 200 mm. The working voltage was 1600 to 2000 V. The counters have an effective dead time not exceeding 10^{-7} sec. The efficiency of the counters for particles with relativistic ionisation reaches 98% in a coincidence scheme with a resolving time of 5×10^{-7} sec. The delay of the pulses due to drift of electrons through the counter gas is less than 10^{-7} . The counters give electrical pulses with amplitudes between 10^{-4} and 1 V. The large difference in the amplitudes requires the use of amplifiers having a wide dynamic range and an amplification of a few thousands. 6-fold coincidences were used and the number of random coincidences in each 6-fold channel was 0.02 pulses per sec. The number of electron-positron pairs recorded per

Card 4/7

SOV/120-58-6-5/32

A Multichannel Pair γ -Spectrometer. II. Description of a 12-channel Spectrometer

sec depended on the efficiency of the spectrometer with respect to the γ -quanta in the measured energy interval and the form of the spectrum and was in the range 0.1 to 10 pairs per sec.

4) Electronic scheme.

A block diagram of the electronic part of the spectrometer is shown in Fig.3. The left-hand portion of this diagram shows 6 co-ordinate counters of the electron series ($a_1 - a_6$), 6 co-ordinate counters of the positron series ($b_1 - b_6$) and 4 selection counters (A' , A'' , B' and B''). Each of these counters in practice consists of a group of counters whose filaments are connected. A recorded electron or positron should pass through 3 counters (1 co-ordinate and 2 selection counters). A pair is recorded if a 6-fold coincidence takes place. Negative-going pulses from each counter are amplified by a corresponding amplifier-converter (Fig.4). These amplifiers have a rise time of 2×10^{-4} sec. Pulses from all the 16 amplifier-converters are applied to the main block which is at a distance of 1.5 m from the amplifier-converters (Fig.5). Pulses from the selection counters are applied to a

Card 5/7

SOV/120-58-6-5/32

A Multichannel Pair γ -Spectrometer. II. Description of a 12-channel Spectrometer

4-fold coincidence scheme while pulses from the co-ordinate counters are applied to mixers and in addition through delay lines to a hodoscopic system consisting of 2-fold coincidence circuits and output univibrators. The pulse at the output of a mixer appears in the presence of a pulse in at least one of the co-ordinate counters of a given series. Pulses from both the mixers and also from the 4-fold coincidence scheme are applied to a 3-fold coincidence scheme which produces the final output pulse. It follows that the latter pulse appears when a 6-fold coincidence takes place, i.e. when a particle passes through at least one of the co-ordinate counters in the electron series, through one of the co-ordinate counters of the positron series, and all the counters of the selection system. The resolving time of the above coincidence schemes is 5×10^{-7} .

5) Method of measurement and treatment of results.
Fig. 7 shows the experimental arrangement. In this figure 1 is the proton trajectory, 2 is the target, 3 is the synchro-cyclotron chamber, 4 is a concrete wall, 5 is a collimator,

Card 6/7

SOV/120-58-6-5/32

A Multichannel Pair γ -Spectrometer. II. Description of a 12-channel Spectrometer

6 is a diaphragm, 7 is a clearing magnet which removes electrons and positrons from the beam, 8 is an additional screen, 9 is the convertor and 10 is the spectrometer electro magnet. Fig.8 shows a typical result obtained for the energy spectrum of γ -quanta from neutral π -meson decays. The mesons were produced by 660 MeV protons at a carbon target. The spectra are measured at an angle of 180-0° to the direction of motion of the protons. G.P.Zorin, B.A.Krasnovidov, L. A.Fadeyev and G.N.Stepanov are thanked for their assistance. There are 8 figures, 4 tables and 7 Soviet references.

AUTHOR: Sinayev, A.N.

TITLE: Utilization of the time interval between successive
input pulses for data-regeneration in CRT memories

PERIODICAL: Pribory i tekhnika eksperimenta, no.6, 1962, 67-69

TEXT: In multi-channel pulse analysers using cathode-ray-tube
memories, the time required for data regeneration can be an
appreciable fraction of the total operating time. The author
suggests several programs permitting this time to be interleaved
with new data introduction. The various methods are distinguished
by the complexity of the logical circuitry associated with the
memory and the maximum rate at which new data can be accepted. *VB*

radioelektronike. T. 2. Ch. 1. M., Gosatomizdat, 1963, 87-106

TOPIC TAGS: storage tube memory, pulse analyzer, multichannel
pulse recorder, radiation detector, synchrocyclotron

TRANSLATION: Block diagrams are presented for the following: a
storage-tube memory unit, a distribution unit of a multidimensional
(pulse-height and time) analyzer, and a distribution unit for a
multichannel system. A detailed analysis of the operation of these

Card 1/2

L 6927-65

ACCESSION NR: AR4039896

circuits is presented. The storage-tube memory unit is adapted to operate in the pulsed mode (to work with the OIYaI synchrocyclotron, with pulse duration 500 μ sec and repetition frequency 100 cps). The pulses enter the memory unit immediately upon arrival, and the pause time is allotted for establishment of the information. The distribution block of the multidimensional analyzer has 256 channels (16 time channels, each containing 16 pulse-height channels). The ratio of the number of time and amplitude channels can be varied. Selection of time channels is with the aid of a time-amplitude converter. The minimum width of the time channel is 1 μ sec. The distribution block for the multichannel system is intended to register pulses from an installation having a large number of radiation detectors. Cases of time superposition of pulses from two or several detectors are not registered. N. Vishnevskiy.

TOPIC TAGS: amplitude analyzer, potentiometer, pulse analyzer, pulse amplitude/EPP-09 recording potentiometer

ABSTRACT: An investigation is made of an amplitude analyzer, similar to the one described in the work of Birulev et al. (RZhFiz, 1964, 2A162), where the recording EPP-09 potentiometer is used as the amplitude analyzer. When the pulse comes to the analyzer input, the carriage of the recording potentiometer travels a distance proportional to the pulse amplitude, and then returns. The dead time and the number of the analyzer channels are determined by the characteristics of the record

Card 1/2

L 09463-67

ACC NR: AR6033770

ing potentiometer. The number of channels can be brought to 127. The pulses at the analyzer input must be positive with an amplitude ranging from 0.3 to 6 v and a duration of 1 to 1.5 μ sec. The instrument works dependably in a temperature range of 0—40C. The integral nonlinearity is less than 0.5 percent. The analyzer is fed with a +8 and -8 v voltage, with a \sim 0.1-percent time and temperature instability, and weighs 0.3 kg. All the analyzer circuits are assembled on semiconductors. A description is given of the block diagram and the operation of all the parts of the instrument. The analyzer is designed for the registration of small events. [Translation of abstract]

TITLE: General-purpose distribution unit for a two-variable analyzer

SOURCE: Pribory i tekhnika eksperimenta, no. 1, 1965, 95-99

TOPIC TAGS: pulse analyzer, pulse analysis

ABSTRACT: Designed with conventional logic elements, flip-flop circuits, triggers, etc., the new two-variable distribution unit is intended for the simultaneous measurement of pulse-height spectra received from two detectors, pulse height-height analysis, time-height analysis, and conventional time analysis. The minimum width of the time channel is 0.2 μ sec, of the pulse-height channel, 0.5 v; dead time is 1 μ sec per channel; differential nonlinearity is 2.5%. The distribution unit is used in conjunction with a 256-channel storage-tube analyzer for experiments on the OIYaI synchrocyclotron and also for experiments with a continuous radiation source. A block diagram of the distribution unit is presented and briefly described. Orig. art. has: 2 figures. [03]

TITLE: Serological investigation of virus strains isolated from
epidemic hepatitis patients

SOURCE: Zhurnal mikrobiologii, epidemiologii i immunobiologii, no.
6, 1964, 120-125

TOPIC TAGS: hepatitis (Botkin's disease), isolated hepatitis virus
strain, virus strains K₃ and 158-kr, serological investigation, serum
neutralization reaction, complement fixation reaction, virus
neutralizing antibody, virus specificity, hepatitis convalescence
period, serum titration

ABSTRACT: Twelve virus strains were isolated from the blood and
feces of epidemic hepatitis patients and an immune serum was
developed for each strain by immunizing rats with virus suspensions.
The neutralization and complement fixation reactions of the 12 serums
showed that 10 of the 12 virus strains were similar in biological and
antigenic properties. Two of these similar virus strains (K₃ and

Cord 1/3

L 6800-65
ACCESSION NR: AP4039589

158-Kr) were used for seroreaction investigations of serums prepared from epidemic hepatitis patients in different convalescent stages. For complement fixation reactions, the serums were diluted with five parts of a physiological solution (pH 7.0) and heated at 60°C for 30 min. For neutralization reactions, serums were taken from patients with serious hepatitis cases (aldolase level of 30 to 40 units or more, transaminase level of 100 units or more, clinical symptoms and enzyme levels not restored by 4th to 5th week of jaundice) and from patients with light hepatitis cases (aldolase level of less than 30 units, transaminase level of less than 100 units, clinical symptoms and enzyme levels restored by 4th to 5th week of jaundice). Findings show that the titers of virus neutralizing and complement fixing antibodies are low in sera of patients with epidemic hepatitis. Antibodies for the investigated virus strains were generally found in the sera of patients during the fourth month of convalescence or later. Virus neutralizing antibodies were found more often in sera of patients with serious hepatitis cases. In many cases, antibodies for the virus strains under investigation were also found in donor sera and sera from patients with different acute infectious diseases. Experimental results demonstrate the feasibility of investigating

ACCESSION NR: AP5021281

6

temperature was determined after B. Ya. Teytel'baum and M. P. Dianov (Vysokomolek. soyed., 3, 594, 1961). The experimental results are shown graphically in Figs. 1, 2, and 3. It is concluded that crystallization processes influence the glass transition temperature of block-copolymers. Crystallization of component with lowest Tg lowers the Tg of the block-copolymer. The latter component acts as an internal plasticizer in the crystallization of the higher melting component of the block-copolymer. Orig. art. has: 3 graphs, 4 microphotographs, and 2 equations.

TITLE: Unsteady state diffusion of a magnetic field in a plasma cooled by solid walls

SOURCE: AN SSSR. Izvestiya. Mekhanika zhidkosti i gaza, no. 4, 1966, 3-8

TOPIC TAGS: plasma diffusion, magnetic field, magnetohydrodynamics

ABSTRACT: The aim of the work was an evaluation of the role of heat conductivity in the diffusion process of a magnetic field in a plasma. The analysis starts with a solution of the linear problem in a cylindrical conductor without taking heat conductivity into account. The problem is solved by the method of integral relationships and by the method of the expansion of the unknown functions in a series; the second method serves to evaluate the accuracy of the first. There follows an analysis of the problem of the cooling of a plasma moving in a tube. An evaluation is made of the maximum permissible time of processes where the cooling does not yet affect the plasma moving in the center of the tube. Finally, the article solves the problem of the diffusion of a magnetic field in a plasma cooled by walls. All the investigations were carried out on the assumption that the processes are one dimensional, that is, the diffusional and thermal layers are assumed to be

Card 1/2

L 06068-67

ACC NR: AP6030103

D
sufficiently thin with respect to the characteristic linear dimension of the plasma sheaf. The plasma is considered as a solid conductor with a conductivity σ and a heat conductivity coefficient λ calculated by the corresponding formulas for a completely ionized gas. Strictly speaking, the method is valid only for thin thermal and diffusional layers. Orig. art. has: 35 formulas and 2 figures.

TITLE:

An Investigation of the Composition of the Hydrocarbons C₆ - the
By-Products of the Catalytic Synthesis of Divinyl From Alcohol
(Izuchenie sostava uglevodorodov C₆ - pobochnykh produktov katali-
ticheskogo sinteza divinila iz spirta).

PERIODICAL: Zhurnal Obshchey Khimii, 1957, Vol. 27, Nr 11, pp. 2927-2931 (USSR).

ABSTRACT:

The investigation of ethyl alcohol in divinyl over a catalyst repre-
sents a complicated catalytic process which is accompanied by a con-
siderable amount of side reactions. In spite of the informative pa-
pers by S. V. Lebedev and Ya. A. Gorin in the field of the catalytic
formation of the combined dienes (C_nH_{2n-2}) from alcohols, their bina-
ry mixtures, and the mixtures of the alcohols with aldehydes and
ketones with regard to the by-products, their composition is by far
not sufficiently investigated. Of the insufficiently investigated
by-products obtained on rectification of hydrocarbons the so-called
hexylene-hexadiene fraction (boiling point 60-90°C) is the object of
the authors' investigation. On further rectification the following
were obtained beside other by-products. 1) hexadiene-1,3. 2) 3-

Card 1/2

An Investigation of the Composition of the Hydrocarbons C₆ - the 79-11-4/56
By-Products of the Catalytic Synthesis of Divinyl from Alcohol.

methylpentadiene 1,3. 3) cyclohexadiene-1,3. Thus the presence
of the combined dienes. 1) hexadiene-1,3. 2) 3-methylpentadiene-
1,3 and 3) cyclohexadiene-1,3 was determined in the hexylene-hexa-
diene fraction of the hydrocarbons, the by-products of the catalytic
synthesis of divinyl from alcohol according to Lebedev, and the way
of their formation was partially suggested.

TITLE: Production of Foam Polystyrene by Means of Unsaturated Low-boiling Hydrocarbons B115/B017
PERIODICAL: Khimicheskaya promyshlennost', 1959, Nr 8, pp 672-674 (USSR)
ABSTRACT: The aim of the investigation made by A. A. Berlin (Ref 1) was the development of a technological process for the production of foam polystyrene as an insulating and building material for radio engineering without using pressure. At present, two main processes are known for the production of foam polystyrene. In the first method foam formers which decompose at increased temperatures (e.g. dinitrile of azodiisobutyric acid and ammonium carbonate) are used, and in the second method (Refs 1,2) polystyrene is saturated with gases or easily volatile solvents. Polystyrene saturated with these products is foamed in perforated molds by heating to 100°. The applicability of the fractions C₄, C₅ and C₆ of stable gasoline as saturation substances and of various methods for the production of polystyrene saturated with saturated easily volatile hydrocarbons is investigated. The method of saturating emulsified polystyrene with butane proved to be the most convenient. Emulsified poly-

TITLE: Viscosity change of the reacting mass in isoprene polymerization

PERIODICAL: Kauchuk i rezina, no. 2, 1962, 1 - 4

TEXT: Results of an investigation on the viscosity change of the reacting mass during isoprene rubber synthesis are submitted. The change is studied with respect to the duration of polymerization, polymer content, isoprene supply conditions and temperature. The isoprene polymerization was carried out in 3-liter autoclaves made of 1X9T18H (1Kh9T18N) steel, with anchor type mixers. The molecular weight of the polymer was determined according to the viscosimetric method and calculated from the formula: $M = 5 + 1.162 h$, where h is the characteristic viscosity. The PB-2 (RV-2) rotational viscosimeter was used for continuous measurement of the viscosity. The viscosity of the ПН-6 (ПН-6) calibrating liquid was measured with a Kepler rheoviscorometer. Experiments showed that one of the main factors determining the absolute viscosity of the reacting mass is the concentration of the monomer. The absolute viscosity does not exceed 30 - 40 poise and coincides with the viscosities of solutions in the

Viscosity change of the reacting mass in

same concentrations of natural rubber and stabilized synthetic isoprene rubber, with a polymer content in the reacting mass of up to 6 - 17% by weight. With further concentration of the polymer, the viscosity of the reacting mass sharply increases, reaching values exceeding 1,000 poise at 20% by weight. The concentration dependence of the viscosity of the synthetic isoprene and natural rubber solutions is the same within the range of up to 20%. For concentrations of the synthetic isoprene rubber solutions in n-heptane of 10, 15 and 20%, the viscosity in the temperature interval $-5 + + 45^{\circ}\text{C}$ decreases by a factor of 2 - 2.3. PARTIAL: The collection of reports is intended for the scientific and technical
personnel of scientific research institutes, plants and schools of higher
education.

CONTENTS: The book is a collection of reports submitted by scientific workers at
plants, scientific institutes and schools of higher education at the third
All-Union Conference on the Automation of Industrial Processes in Machine
Building and Automated Electric Drives in industry held in Novosibirsk on
May 12-16, 1979. The Conference was called by the Academy of Sciences USSR, the
Soviet USSR (State Planning Commission USSR), the Ural Scientific Council of the
USSR (USC) (State Planning Commission USSR), the Central Committee on Automation and
Machine Building, and the National Polytechnic Soviet USSR (State Committee on Automation and
Machine Building) and the National Polytechnic Soviet USSR (Scientific Institute
of Technical Control of Automated Electric Drives), the NII (Institute of Automation and Telemechanics
of Ministry of Machine-Building USSR), the IAT (Institute of Automation and Telemechanics)
of the Academy of Sciences USSR, and the Institute po tekhnologii mashinostroyeniya
and avtomaticheskogo upravleniya (Institute of Technology of Machine
Building of the Institute of Science of Materials of the Academy of Sciences USSR).
It was the purpose of the Editorial Board to organize the reports in such a way which
would ensure a relatively systematic presentation of theoretical and practical
problems relating to electric drives and automatic control of industrial mecha-
nisms used in various branches of industry. Each problem of automated electric
drives and their solution are outlined. The book also contains articles on electro-
mechanical and means of automation. Considerable attention is paid to active
current automatic control systems, including systems with semiconductor devices
and magnetic amplifiers, and to computers intended both for the analysis and the
synthesis of linear and nonlinear automatic regulation and control systems. Some
works already published in journals or official publications have been compiled
and abridged, others which have appeared in volumes V or VII of Transactions
in the journal "Mashinostroyenie" are cited with an asterisk. No personaliza-
tion is mentioned.

Regulyator tolshchiny polosy na nepreryvnom stane kholodnoy prokatki (Strip Gage Controller on the Continuous Cold-Reduction Mill) Sverdlovsk, Metallurg-izdat, 1961. 76 p. 3150 copies printed.

Reviewer: S. A. Vorob' yev; Ed. of Publishing House: M. M. Syrchina; Tech. Ed.: Ye. D. Turkina.

PURPOSE: This booklet is intended for technical personnel concerned with the automatic control of manufacturing processes.

COVERAGE: Problems involved in building up a control system for the gaging of strip on a continuous cold-reduction mill are discussed. The constructional elements of a gage controller on the entry side of a continuous high-speed mill are examined in detail, and the performance of this controller during mill

Highly critical review of subject book. Author did not test a single crane motor, either in laboratory or in industry. All of his calculations (most of which were erroneous) were for models. Concludes that publishing house made a mistake in publishing book.

TITLE: The Effect of Voltage Fluctuations on the Operation of an Alternating Current Crane Motor (Vliyanie kolebaniy napryazheniya na rabotu kranovogo dvigatelya peremennogo toka)

PERIODICAL: Elektrичество, 1958, Nr 3, pp. 19- 22 (USSR)

ABSTRACT: Here it is tried to give a technical reasoning for the selection of the admissible voltage fluctuation limits in the feeding of crane motors, beginning with the analysis of their voltage dependence of mechanical and thermal characteristics. The analysis is applied here to the motors of the series MT, can, however, also be used for other induction motors with other quantitative conditions. The effect of the voltage fluctuation on the following motor operation characteristics is investigated: 1) The adjusted rotation speed at given load; 2) The maximum moment; 3) The energy losses, and therefore also on the heating of the motor. Comprisingly, the following is said: In planning drives with crane motors one should not formally stick to the

Card 1/2

105-58-3-4/31

The Effect of Voltage Fluctuations on the Operation of an Alternating Current Crane Motor

amount of the admissible voltage fluctuation of $\pm 5\%$ of the nominal value. In many cases the taking into account of the concrete working conditions in the motor admits the extension of these limits and the relieving of the power supply at the cost of a greater voltage drop. In special the limitation of the voltage drop is not determined by the motor, but by the steering device in normal cranes where in the selection of the motor the heat conservation is the decisive element, whereas the pull-out torque is not exploited by far. Under all circumstances the voltage drop is not to surpass 15 % in the case of a possible maximum circuit load, since otherwise an exact operation of the steering device is not guaranteed. There are 4 figures.
